An emulsifier is a substance that acts as a stabilizer. In systems like oil and water, emulsifiers stabilize two or more immiscible compounds. Commonly added to bakery goods, including bread, cake and cookies, emulsifiers can be plant or animal based or commercially produced. There are two types of emulsions:

**Water-in-oil emulsion (W/O), e.g., butter**

**Oil-in-water emulsion (O/W), e.g., milk**
What is the function of emulsifiers in baked goods?

The presence of emulsifiers in high volume baking is essential to keeping the quality of baked goods consistent throughout the entire process.

Here's how they impact different products

Bread and Ferment Products: ²
- Higher hydration
- Dough strengthening
- Improved flexibility for machinability
- Finer and softer crumb
- Improved crumb uniformity
- Better resilience at the slicer
- Extends shelf life

Cakes: ²
- Keeping a consistent specific gravity
- Tolerance to processing
- Prevent coalescence of cells and structural collapse
- Uniform cell structure
- Higher volume

Cookies: ³
- Better machinability
- Controls cookie spread
- Less crumbly
- Less friable
- Maintains texture over shelf life

Icing & Frosting: ³
- Improves stability to temperature fluctuations
- Prevents oils from seeping out over the product's shelf life
- Prevents crystal formations
- Provides sharper designs with better edges
- A better mouthfeel and texture

Pastries: ³
- Emulsifiers in the pastry shortening gives better flexibility and machinability to the shortening, resulting in better volume for an improved flakiness
- Prevents water migration and provides a better crisp
# Emulsifiers Commonly Used in Baking

What's the best way to replace an emulsifier?

Since the emulsifier’s main function is to stabilize the food system, any ingredient that can accomplish this function has the potential to replace a specific emulsifier. Transglutaminase and hydrocolloids are common emulsifier alternatives because they are more label friendly. Plant proteins which can provide emulsifying properties are also used to substitute emulsifiers.

**Enzymes (eg: phospholipase, transglutaminases):**

Works on fats and protein molecules to improve dough texture, volume and gas retention. They do this by catalyzing protein or peptide bonds for polymerization.

**Starch (eg: modified corn or wheat starch):**

Modified or pre-gelatinized starch granules can absorb water at a lower temperature and swell to increase the viscosity of dough or batter. An increased viscosity stabilizes the food system.

**Protein (eg: wheat gluten, whey protein, egg whites, soy isolates):**

Protein is mainly responsible for strength, water-holding, foaming, flavor and color of bakery goods. It is the building blocks of any food system.

**Hydrocolloids (eg: carboxymethyl cellulose, carrageenan, xanthan gum):**

Hydrocolloids are not really emulsifiers due to lacking of lipophilic and hydrophilic linkage in the structure. Hydrocolloids molecules cannot flexibly cover the interfaces on oil-water mixtures quickly to create a stable emulsion because of large molecules and complex size. Hydrocolloids can still functionalize as emulsifiers by increasing the viscosity of water surface or by interaction with surface-active substances. Some well-known hydrocolloids include gum arabic, methylcellulose (MC), hydroxypropylmethylcellulose (HPMC) and propylene glycol alginate (PGA).

Arise 8100 can be used as an emulsifier replacer. Learn More. Sponsored by MGP
What is a suitable clean label emulsifier for my slow ferment pizza dough?

With fermented products, an increase in fermentation time, will result in a lower pH due to the production of acids. Dough systems become more unstable when it becomes more acidic. Therefore, suitable emulsifiers like DATEM are usually used to stabilize the system. The best way to replace DATEM in this situation would be to try a sunflower or soy lecithin, with enzymes, depending on the formula.

Enzymes such as phospholipase and transglutaminase can be used to modify the dough behavior and improve the volume, texture and structure of baked goods. These enzymes catalyzes cross-linking between proteins and starch chains, releasing the sugars. This will also help improve yeast fermentation.

Glucose oxidase is an enzyme which catalyses the oxidation of glucose to hydrogen peroxide and D-glucono-δ-lactone. The removal of glucose through the catalyzation allows free glucose for better fermentation. Lastly, ascorbic acid can also be used similarly.

How can I keep my flat bread from cracking?

Cracking is caused by loss of freshness and moisture migration which is a result of staling. Firstly, thermal profile your flat bread product and make sure that you are not overbaking it. Emulsifiers can act as anti-staling agents through increased dough stability and crumb softening. DATEM and SSL are typically used for this function in bread.

A product called Arise (eg., Arise 5000, Arise 6000, Arise 8100, Arise 8200) from MGP is available for this application by increasing the softness and diameter of flat bread. Enzyme blends from ingredient suppliers can do the same. Gums (gum arabic, carboxymethylcellulose, xanthan gum) are also helpful since gums can retain moisture which keeps the bread flexible.\(^4\,^5\)
**What emulsifiers can I use in eggless cake to make it soft, light and fluffy?**

Eggs play an important role in cake batter, in creating structure and stability, coagulation, emulsification, foaming, texturizing, softness, and color.\(^6\)

In order to replace this function, a combination of alpha dextrins, lecithins, hydrocolloids, gluten, and/or modified starches can be used. Arise can partially replace eggs in cake. Sponsored by MGP.

**What emulsifiers can I use to make sliced bread remain fresh?**

Freshness of bread is prolonged by the high moisture content. However, the higher the moisture content of fresh baked breads, the greater the effects of staling. Thus, emulsifiers functionalized as anti-staling agents can be added in the dough for softening and moistening the bread. Common emulsifiers used in sliced bread to remain fresh include hydrocolloids such as carboxymethyl cellulose, guar gum and xanthan gum.

**What common bread emulsifiers are used in high volume bakeries?**

Sodium stearoyl lactylate (SSL), Diacetyl tartaric acid ester of mono- and diglycerides (DATEM) and Mono & Diglycerides. The above emulsifiers improve structure, helps with machinability and thereby produces a higher volume. A higher volume would increase the softness of the product. Many consumers perceive a softer product as a fresher product. Some common enzymes used in bakeries are transglutaminase and phospholipase.
